

# Classifying Authorial Perspective

Rick Szostak

University of Alberta, Department of Economics,  
Edmonton, Alberta, Canada, T6G 2H4  
<rszostak@ualberta.ca>

Rick Szostak is professor of economics at the University of Alberta. His research has focused for the last fifteen years on facilitating interdisciplinary research and teaching. Knowledge organization has become the dominant element in that research agenda, and he has authored two books and several articles that develop classifications of things studied, theories and methods applied, types of data, ethical perspectives, research practices, and relationships. He has contributed to the Integrative Levels Classification and is developing the Basic Concepts Classification. He has argued in several places for the value of a classification grounded not in disciplines but in the things we study and the relationships among these. He is working with others on a book about interdisciplinary knowledge organization. See <https://sites.google.com/a/ualberta.ca/rick-szostak/>

Szostak, Rick. **Classifying Authorial Perspective**. *Knowledge Organization*. 42(7), 499-507. 14 references.

**Abstract:** The paper motivates and outlines a classification of authorial perspective. It shows that there are a manageable number of both dimensions and possibilities along these dimensions. It shows that this classification is broad in coverage, capturing diverse elements of perspective. It discusses questions of feasibility in application and how these might be investigated. But such empirical investigation is impossible until a classification has first been developed.

Received: 23 June 2015; Revised: 19 August 2015; Accepted 31 August 2015

Keywords: classification, authorial perspective, dimensions

## 1.0 Introduction

Information scientists have long recognized the potential benefits of classifying authorial perspective. In particular, this would help users evaluate the potential relevance of works (Clavier and Paganelli 2011). And of course it would alert users to potential biases in the text (Gutierrez and Martinez-Avila 2014). Lukoianova and Rubin (2013) suggest that it might also enhance detection of purposeful deception. In addition, such a classification would facilitate communication both within and beyond social groups (Szostak 2014). Individuals might wish at times to consult only works reflecting a particular perspective; if so this is a desire that knowledge organization systems should serve. We might hope that users will often be interested in exploring particular issues from multiple perspectives; this task too will be aided by classifying works in terms of authorial perspective. But such a classification has never been developed.

One problem is that there are a variety of dimensions—rhetorical, ethical, epistemological, and so on (see

below)—along with which authorial intent or perspective might be evaluated. It might be worried, then, that it would prove too costly to classify works by perspective. In the contemporary world, in which the costs of data entry and storage are much lower, this may no longer be an unsurmountable barrier. Classifying works by perspective may prove especially feasible if most works need only be classified along a subset of these dimensions.

The approach taken to identifying dimensions in this paper is largely inductive; we will address several dimensions that have been identified in the previous literature. We will, though, in the next section suggest a deductive approach to evaluating whether we have achieved an appropriate breadth in our classification. That is, we can imagine a set of questions that illuminate distinct aspects of authorial perspective. The inductive approach has the advantage of indicating that there is some consensus around the nature of key dimensions.

A second problem then involves identifying a set of possibilities along each dimension. It might be worried that there are innumerable such possibilities. We will de-

vote much of our attention to identifying possibilities along each dimension. We will find that the number of possibilities is not only countable but also manageable in size.

A third potential problem is that it may prove challenging in practice to establish authorial perspective of a particular work along at least some dimensions. The degree of difficulty can only be estimated once a classification of authorial perspective has been developed. This paper will focus on addressing the first two problems, and thus set the stage for an evaluation of the scope of the third. We will, though, briefly address strategies for classifying the perspective of particular works toward the end of the paper.

In the next section we propose three guiding assumptions for classifying authorial perspective. We will in the succeeding (and much longer) section employ these three simple assumptions in order to generate a multi-dimensional classification of authorial perspective. We will address in turn a variety of dimensions that have been suggested, and show how each can be addressed. Examples of synthetic constructions utilizing the Basic Concepts Classification (BCC; see Szostak 2013) are provided throughout, but similar constructions could likely be provided from other general classifications. It should be stressed that the use of BCC for illustrative purposes reflects the author's familiarity with that classification; we will discuss briefly toward the end of the paper whether other classifications could be employed to the same effect. The various dimensions, and possibilities along dimensions, are summarized in Table 1. As promised above, a brief discussion of practical considerations follows. This is followed in turn by a concluding section.

## 2.0 Three guiding assumptions

We propose three helpful guiding assumptions:

- 1) Since authorial perspective is an element of human behavior, it should be the case that what we need to capture in a classification of authorial perspective with respect to both dimensions and possibilities along dimensions should already be classified within a general subject classification (where "general" is taken to mean comprehensive in coverage). That is, a general classification should already contain terms for every possible aspect of authorial perspective. One important implication of this assumption is that we can potentially deal with authorial perspective synthetically without needing to add new schedules to our classification. (Note that our emphasis on general classification here and elsewhere in the paper need not imply that we cannot identify authorial perspective within

domain-specific classifications; in such a case, though, we would likely need to employ many terms not otherwise employed elsewhere in the classification.)

- 2) Kleineberg (2013) has recently urged us to explore the "how, what, and why" of a work. We can usefully expand this suggestion to include "who, where, and when." An author's perspective might be anticipated to reflect who the author is, what they are doing, why they are doing it, how they choose to proceed, and when and where they operate. In conjunction with assumption 1, this guides us to explore existing classifications of personality characteristics, cultural values, political ideologies, and so on. Szostak (2004, ch. 5) showed how these "5W" questions could illuminate various sources of scholarly bias. We can ensure that there is appropriate breadth to our classification if it captures elements of who, what, where, when, why, and how. As journalists will attest, different W's are more important for different texts. As we will discuss below, it is thus likely that only a subset of possible dimensions will be important for particular works.
- 3) If we face numerous dimensions and possibilities, and can have recourse to diverse schedules within a general classification, then another useful starting assumption is that a synthetic approach will serve us best here. A synthetic approach to classification has been commonly urged in the literature since at least Ranganathan (1937), though less commonly employed in practice. Yet even enumerative schemes have had some success introducing synthetic elements.

These assumptions, we hope, do not require more extensive justification. Yet they have, as we shall see, important implications for the classification of authorial perspective. It is useful to briefly review how each assumption will be employed in the next section:

We will employ synthetic constructions (assumption 3) throughout in identifying possibilities along each dimension of authorial perspective. These synthetic constructions will rely wherever possible on terms already available within at least one general classification, the BCC (assumption 1). In our discussion of each dimension we will address which of the 5W questions are engaged (assumption 2); we then at the end of the next section summarize our coverage of each of the 5W questions. As noted in the introductory section, this approach allows us to provide a deductive check—for the 5W questions are a fairly exhaustive set of questions that we can logically ask about authorial perspective—on our largely inductive effort of investigating dimensions that have been suggested in the previous literature. The combination of inductive and deductive ap-

proaches can assure us that the suggested classification of perspective is reasonably exhaustive.

### 3.0 Addressing particular dimensions

Szostak (2014), drawing on many others, suggested a variety of possible dimensions. These can be addressed in (roughly) the order of increasing difficulty.

#### 3.1 Discipline/Field

The disciplinary (or interdisciplinary) home of the author can be indicated. A general classification should have a place for all such fields. It may also be useful to indicate the institutional home of researchers: university, public research center, non-profit, private, and so on.

#### 3.2 Methods employed

The classification can first indicate which of the dozen broad methods any author employs (Szostak 2004): experiment, survey, interview, statistical analysis, modelling, classification, examining physical traces, mapmaking, observation, textual analysis, intuition/experience, and hermeneutics/semiotics. This list was derived from a broad survey of the literature; it is unlikely that there are alternative methods that are not best seen as a subclass of one of these. Particular techniques within these methods can then be further distinguished. For example, interviews may be structured or open format, individual or group, and may also be distinguished in terms of the number of interviewees; particular interview situations such as doctor/patient consultation can be designated. The BCC provides a detailed classification. In developing the BCC it was found to be straightforward to identify the most common techniques within any method. It should be possible to indicate when a researcher pursues mixed methods, followed by the methods that are mixed.

#### 3.3 Theoretical orientation

Any theory the author explicitly employs can be referenced here. Gnoli and Szostak (2008) discussed how best to classify theories, and the Integrative Levels Classification (ILC) and BCC both contain detailed classifications of theory types. The key point here is that—since theories evolve, theory names are ambiguous, and new theories are created with some regularity—it is important to classify by “theory type” as well as by theory name. Gnoli and Szostak showed both the utility and feasibility of employing a five-dimensional classification of theory types. Notably, these were grounded in the 5W questions recommended above: “who” is the causal agent within a

theory, “what” does the causal agent do, “why” does the causal agent do this (which for intentional agents involves classifying different types of decision-making, for non-intentional agents it means examining the agent’s inherent nature), “where” does the causal process occur (that is, how generalizable is the theory), and “when” does the causal process occur (or in other words how does the causal process unfold through time: change in a particular direction, a new equilibrium, cyclically, and so on). As above, this list of questions provides a reasonably comprehensive survey of key attributes of any theory. For each of these five dimensions/questions a handful of key answers can be identified. Causal agents, for example, can be either intentional or non-intentional, and either type can comprise individuals, groups, or relationships (Szostak, 2004, derives and justifies a small set of possible answers to each of the 5W questions). A work employing neoclassical economic theory could be classed as neoclassical, but also as emphasizing intentional individuals, rational decision-making, actions, equilibrium outcomes, and a high degree of generalizability; in the (unlikely) event that neoclassical theory evolves into something different over time classification in terms of theory type will still indicate the precise nature of the theory employed in a particular work. With respect to other theories that do not give precise answers to each of the 5W questions, classification in terms of theory type serve to clarify which version of the theory is applied.

Classification in terms of theory types makes it possible that even works that do not explicitly employ (or admit to employing) a particular theory might still be classified along this dimension. That is, it may be possible to determine the type of agent or decision-making or activity or process envisioned, and also the degree of generalizability proposed.

#### 3.4 Ideological outlook

There are only a handful of ideologies commonly referenced in the literature: classical liberalism, libertarianism, pragmatic liberalism, conservatism, socialism, communism, fascism, anarchism, and nationalism are the most common (and are listed in BCC), though a few others might be added. There is a fair bit of agreement regarding titles of the main ideologies, but more disagreement regarding the defining characteristics of each. One stratum for addressing these definitional challenges would be to also reference more precise attitudes toward particular political issues (e.g. pro-choice).

We promised above to review as we proceeded how each dimension reflects the 5W questions. It is worth noting here that the first four dimensions address different aspects of “why” an author might have written a par-

ticular text. The method dimension, and to a lesser extent the theory dimension, also speak to “how” this was done.

### 3.5 Ethical outlook

Authors might be distinguishable in terms of the types of formal ethical approach they take (Szostak 2004, 194–8): consequential analysis, deontological (focus on rules), virtue/value oriented, tradition-based, or intuition-based. Some would argue that some other approaches, such as the ethic of care, do not fit cleanly in any of these five classes. We could investigate whether any philosophical approach is not captured by the procedures suggested below. If this were to be the case we could then identify how to treat works pursuing that approach. Note that each of these five types of ethical analysis opens up a broader set of possibilities that are best addressed synthetically but with recourse to diverse elements of a general classification.

- i) Consequential analysis most often focuses on economic outcomes but at times focuses on political or social or aesthetic outcomes. A perspective might be denoted (perspective)(consequentialist)(beauty). Potentially an author might be consequentially disposed toward phenomena across diverse subclasses of a general classification. The synthetic approach obviates any need to enumerate these here.
- ii) The most common rules are the golden rule and various rights. The golden rule deserves treatment somewhere in a general classification. As long as “rights” appears also, specific rights might be captured synthetically: Right to property.
- iii) One of the challenges of virtue analysis is that there are a host of virtues/values one might invoke (which often compete, though far from always). The BCC provides a comprehensive list of “cultural values”—derived also using a mix of induction and deduction—that could be employed synthetically here.
- iv) If an author stresses tradition we could then synthetically specify the country, ethnic group, religion, or social group whose traditions are invoked. Many traditions are broadly shared; this too can be captured synthetically: (tradition)(all)(major)(world religions).
- v) Intuition suggests that we look either at personality dimensions or human emotions. These are each classified in some detail in the BCC. There is a fair bit of consensus among psychologists regarding both the major personality dimensions and the key emotions,

though of course this consensus may shift with new research.

It is noteworthy that in exploring ethical perspective, we have addressed “who” the author is (personality dimensions, emotions), and “when” and “where” they are situated (traditions, ethnicity, etc.). (We will likely have little need to classify here the myriad shortcomings in perception or cognition that afflict us all, nor particular personality “defects” that would detract from science [unless some authors confess to these, if conscious of them] (Szostak 2004).)

Philosophers have, of course, debated at great length the details of the three formal types of ethical analysis. They have in so doing developed myriad variations of each. These can in general be captured synthetically. Nevertheless we may wish to identify particular variants if literary warrant justifies these. There is, though, a tradeoff between detail and simplicity of the classification.

### 3.6 Epistemological outlook

Epistemology addresses both the possibilities of human understanding and questions of how we can/should best attempt to enhance our collective understanding (if this is judged possible). We capture here elements of why an author writes, what they write, and how they proceed. How can we best get a handle on key epistemological concerns? The Toolbox project (Eigenbrode et al. 2007; Looney et al. 2014) centered at the University of Idaho has tried to enhance interdisciplinary collaboration by exposing and then mitigating the hidden epistemological assumptions that would otherwise hinder collaboration on interdisciplinary research teams. They have to this end developed and revised a questionnaire that they give to researchers. The purpose of these questions is to identify the key elements in differing epistemological approaches. Their research thus highlights the sort of epistemological distinctions that are important to (especially interdisciplinary) scholars. And of course their questionnaire is grounded in their own search of the epistemological literature for key questions to ask. Though they ask questions about a researcher’s general attitude toward research, the questions could also illuminate the epistemological nature of particular works. The questionnaire has six main sections:

- Motivation: They distinguish basic versus applied research. This we could easily do. They also speak of advocacy. This could be captured synthetically in association with what is being advocated: (advocates)(war)
- Methodology: Does the research have a guiding hypothesis? We could perhaps best capture this element by distinguishing deductive from inductive research.

They also explore openness to mixed methods. This was addressed above when discussing methods. Finally they explore the spatial and temporal extent of research. We can hope that research specific to a particular time and place will have these signified within the subject heading. Beyond that we can note that the degree of generalizability is one of the dimensions along which theories should be classified.

- Confirmation: What types of evidence are considered valid? We can best address this consideration by indicating the method(s) used in particular research. It might also be both possible and desirable to treat the type of data employed (Szostak 2004 discussed classifying data, but did not at that time develop an operationalizable classification.) Toolbox also asks whether strict replication using the same method and data is sought or rather evidence from different methods and data. For categorizing particular works the most important consideration likely involves signaling “replication.” (Mixed methods were addressed above.)
- Objectivity: Is objectivity possible? Is objectivity desirable? This is certainly one of the greatest epistemological conflicts in the contemporary academy. Yet in practice scholars either stress the possibility of objectivity or the inevitability of subjectivity, or lie somewhere on a continuum between these two positions. We could employ descriptors such as (believes)(objectivity) and (believes)(subjectivity); and to capture the continuum between these possibilities: (believes)(some)(objectivity).
- Values: Can values be excluded from research? Should values be driving research? For our purposes, the fact that we can signal values that drive a particular research project or report (see above, virtue ethics) may suffice here. The previous bullet regarding subjectivity already tells us something important about whether the author believes it possible to exclude values from research.
- Reductionism versus emergence: Do researchers believe that all phenomena can be understood in terms of constituent elements? While an important epistemological question, we can avoid it. The relevance of a work in this respect will be adequately signaled by a subject classification that accurately captures the causal relationships being investigated. The same can be said of a related epistemological question: to what extent can we isolate particular causal relationships from external influences?
- Reality. In later versions of the questionnaire a question(s) about attitudes toward reality have been added. Do research results reflect (mostly) the real world or researcher perspective? We might wish to distinguish “realist” from “constructivist” and perhaps even “optimist” and “pessimist.” Realism and constructivism

are, at least at present, the major approaches that are contrasted in this context.

### 3.7 *Aesthetic outlook*

Beyond the example cited under consequential analysis, we may need little more here than a synthetic (perspective)(X)(is beautiful). Such a statement would simultaneously signal that aesthetic evaluation is an important component of the work and highlight a/the key element of the aesthetic approach taken. Note that “X” here might represent a thing (say, waterfalls) or a quality (say, symmetry). The BCC has an entire schedule of adjectival qualities that might be applied in this synthetic approach (Other general classifications that are enumerative in approach may have a less extensive list of stand-alone qualities to employ here.) Works about art might be distinguished as to whether they are works of connoisseurship, criticism, and so on (see Clavier and Paganelli 2011). Different aesthetic theories would be captured above under theory.

### 3.8 *Rhetorical strategies*

Here we address “how” an author strives to convince (as well as elements of “what” not captured by the main arguments of the work). And various information scientists have addressed elements of rhetorical strategy (generally without using that phrase). Clavier and Paganelli (2011) have suggested that we distinguish criticism, agreement, consensus, and so on. Feinberg (2011) distinguished logic, appeal to beliefs, and adjustment of formal elements.

Ideally we could refer here to some consensus list of key rhetorical strategies identified by the community of rhetoricians. There is indeed some consensus that there are at least 100 such strategies, and a fair bit of consensus on what each of these involves. It should be noted that a variety of rhetorical strategies, such as alliteration, operate generally at the level of particular phrases rather than entire texts (though shorter texts, and especially poetry, provide important exceptions). We may find it desirable to stress the subset of rhetorical strategies that operate at the level of (longer) texts.

A distinction is often made between three broad rhetorical strategies. The first, called “logos,” relies on logical argumentation (we may wish to capture the inductive versus deductive distinction here). The second, “ethos,” focuses on efforts to establish the author’s authority. The third, “pathos,” involves appeals to emotion. Each of these can each be readily identified in a classification. (The distinction made by Feinberg 2011 echoes this tripartite distinction.)

A distinction is often made among (at least primarily) types of “logos:”

- analyzing cause/effect
- compare/contrast
- define
- classify
- describe person/place/thing
- explain how something happens
- narrate a story

For “pathos,” synthetic reference to particular emotions should be feasible: (pathos)(fear). For “ethos” synthetic links might be imagined to any justification for authority: occupation, education, social status, and so on.

A variety of more particular strategies likely deserve treatment: argument from analogy, metaphor, argument from absurdity, understatement, thought experiments, litotes, and inference to the best explanation. The differences in rhetorical purpose stressed by Clavier and Paganelli (2011) also deserve reference. These can all be captured synthetically within the BCC. In particular the BCC contains a (expandable) list of “types of statement” drawn from the critical thinking literature (though, like alliteration, these may prove less applicable to long texts). Note that while rhetorical strategies are applied most often to written texts, they can also be applied to conversations and visual media. It is thus desirable that the same terminology be employed across a general classification.

Though there may be as many as 100 distinct rhetorical strategies, the rhetorical approach of the vast majority of texts can likely be captured by reference to the tripartite distinction of logos, ethos, and pathos, followed perhaps by some reference to the dozen or so strategies listed in the preceding three paragraphs. Though rhetorical strategy is thus one of the more challenging dimensions to address, it is nevertheless manageable in scope. As always in knowledge organization literary warrant can be employed to identify the most commonly employed rhetorical strategies, though the synthetic approach allows even less important strategies to be signaled when necessary.

### 3.9 Others

Soergel (1985) noted that it would be useful to designate the level of previous understanding required for a text. The easiest way forward here might be to reference the degree of education assumed by the author, perhaps synthetically linked to particular fields of study. Again, these elements should already be present within a general classification.

A key aspect (Szostak 2004, 186-91) of “when” not addressed above involves how a particular work fits

within the broader academic conversation. This is perhaps best captured through bibliometric analysis of citations. There might be some limited value in signaling “revolutionary” works, though authors tend to exaggerate the revolutionary character of their research.

### 3.10 Reviewing the 5W questions

The “who?” dimension is addressed both when identifying disciplinary affiliation and in embracing personality dimensions and emotions under the intuitive approach to ethics. Disciplinary affiliation also indicates “when?” and “where?” an author is situated, as does the treatment of tradition within ethics. (Szostak, 2014, addresses the pros and cons of classifying the ethnicity, class, gender, or sexual orientation of authors, and leans toward not doing so.) The “what?” dimension is captured in several places, notably method, epistemology, and rhetoric. “Why?” is even more extensively addressed in discipline, theory, method, ideology, ethics, and epistemology. And “how?” is dealt within discipline, theory, method, epistemology, and rhetoric. Though the coverage of who, where, and when is limited, key elements of each is covered. What, why, and how are arguably far more important to the purposes of authorial perspective as outlined in the paper’s introduction: they speak to a work’s relevance, likely biases, potential for deception, and intended audience. It can thus be concluded that the proposed classification of authorial perspective is reasonably exhaustive in coverage.

## 4.0 Commentary

Gutierrez and Martinez-Avila (2014) suggested that perspective can often best be seen in terms of a continuum between two dichotomous positions. This is true for some of the dimensions above: the generalizability dimension within theoretical perspective, the agreement versus criticism distinction of Clavier and Paganelli (echoed by Gutierrez and Martinez-Avila) and perhaps the values and objectivity dimensions within epistemology and some others. Such continua represent a small challenge to the classificationist; the easiest strategy is likely to divide the continuum into segments and apply different notations to each segment, and likely provide separate notations to the endpoints. It should be stressed, though, that the vast majority of the dimensions above are not continua but lend themselves rather to a manageable number of distinct possibilities.

Gutierrez and Martinez-Avila (2014) also suggest that it is possible to signal perspective in value-free terminology. This has been the intent above. There is value in a wide variety of different perspectives. Though some users may choose to pursue works from only one perspec-

tive, it can be hoped that many users will use the proposed classification in order to familiarize themselves with multiple perspectives.

Smiraglia (2001) stressed that it is not possible to separate the style from the substance of a work. Most of our classificatory effort with respect to subject classification naturally focuses on the substance of a work. And many elements of authorial perspective likewise address the substance of a work (especially the theory and method employed). But the rhetorical dimensions in particular, and also often discipline, tell us much about style.

## 5.0 Summary

The various dimensions and possibilities along dimensions are summarized in Table 1.

## 6.0 Some practical considerations

Should authorial perspective be handled in one or multiple metadata elements? Or should it somehow be handled

within subject classification? We think it advisable to distinguish authorial perspective from subject classification. It is nevertheless advantageous to employ the same terminology for each. We lean toward treating all elements of perspective within one metadata element, since each dimension addresses different aspects of an overall perspective.

As was hinted at the outset, we should appreciate that different dimensions will be of different importance for different works. One point to stress here is that each of the dimensions discussed above would be useful to some users in evaluating some works. Rather than allowing only some dimensions to be applied to some fields, in an interdisciplinary world it makes sense to allow any dimension to be applied to any work. Yet the fact that in practice some dimensions can be ignored when classifying a particular work should significantly reduce the costs of classifying with respect to authorial perspective. The classifier can determine whether classification of a particular work along a particular dimension is worth the effort.

The paper has used examples from the BCC to illustrate how each element of the classification of authorial

Main Dimensions	Subsidiary Dimensions	Possibilities along Dimensions
Discipline		Disciplines and Fields
Methods		12 main types, particular techniques
Theories  [Note: need to classify by both theory name and theory type. The latter can be classified along five dimensions.]	Who is the agent?  What does the agent do? Why does the agent do this?  Where does the process occur? When does the process occur?	Intentional/non; individual, group, relationship Act, react, form attitude Innate nature if non-intentional; 5 types of decision-making if intentional Continuum of generalizability Equilibrium, cycle, change in one direction, stochastic
Ideology		Several distinct ideologies; also issue-specific attitudes
Ethics	Consequentialist Deontological Virtue/value Tradition Intuition	By desired consequence Golden Rule, or particular rights Particular values Particular groups or general Emotions, personality dimensions
Epistemology	Motivation  Methodology Confirmation Objectivity/Subjectivity Realism	Basic versus applied; advocate particular outcomes Deductive/Inductive?; Mixed? Replication?; Data? Continuum Realism, constructivism; maybe optimism, pessimism
Aesthetics		What is beautiful?
Rhetoric	Logos   Ethos Pathos Particular strategies	Analyze cause/effect; define; compare/contrast; classify; describe person/place/thing; explain how something happens; narrate a story Occupation, education, etc. Link to emotions A dozen or so
Target knowledge level		Education level assumed, by field if necessary

Table 1: The classification of authorial perspective.

perspective could be actualized. The BCC was used because of the author's familiarity with it. The reader may wonder if other classifications might also support such a treatment of authorial perspective. This would almost certainly be the case with the Integrative Levels Classification, which is also synthetic in approach. Enumerative classifications, with often complex subject headings, may not always provide the simple terminology that is synthesized into descriptions of authorial perspective. This challenge will likely be greatest with respect to adjectival qualifiers (see above). As was noted above, even domain-oriented classifications may be able to indicate authorial perspective. This will require, though, that the terminology necessary to classify perspective will have to be generated specifically for that purpose rather than simply borrowed from the subject classification itself.

How might the various elements of authorial perspective be identified in practice? It could be that authors might be asked to self-declare (though they might lie). Authors wishing to signal relevance might have an incentive to identify their perspective. It is then important that the classification be easy to comprehend and navigate. Some authors may choose for a variety of reasons not to indicate their perspective. Crowd-sourcing is another possibility, though the risk that a work might be purposely mis-classified would need to be patrolled. There is of course a danger that cross-indexer consensus might prove particularly low along some dimensions. We cannot proceed to measure the degree of indexer consistency until we have developed a potentially useful classification of perspective. The purpose of this paper has been to develop such a classification. It should be stressed that the different possibilities along each dimension above are precisely defined. Works of non-fiction in which an author is making a particular argument from certain premises should generally prove feasible to classify. Debate often rages regarding the intentions of the authors of fiction, of course; if authorial perspective is to be addressed there it may be desirable to allow scope for disagreement.

In addressing epistemology above, we noted that scholars disagree regarding the possibilities of objectivity. The practically-oriented field of knowledge organization has been forced to appreciate the ubiquity of subjectivity but also that there are strategies that allow many classificatory projects to proceed despite the existence of subjectivity. It may be tempting to simply assume that authorial perspective is too inherently subjective to allow classification. This is clearly not the case for many elements: discipline, method applied, and theory applied in particular. It may not be the case for any elements if the author honestly declares these. Only empirical analysis can tell us whether we can overcome subjectivity to the degree required for the purposes of a classification of authorial perspective; it may

or may not prove to be the case that the answer differs by element and/or by scholarly field. We should not assume the results to empirical questions but evaluate these carefully.

Having noted that different elements of authorial perspective might be of differing importance across the academy, we might then wonder whether a domain-specific approach to classifying authorial perspective would be advantageous. But each of the dimensions addressed in this paper likely applies across many fields and some—there are always rhetorical strategies of some sort—apply across all. Some possibilities along dimensions may be rare in some fields—appeals to emotion in chemistry perhaps—but the cost of allowing for this possibility is low compared to developing myriad domain-specific classifications. And our general classification serves to better capture the unusual scholar who brings new approaches to a subject.

Having suggested crowd-sourcing as a possibility, we might also wonder if we could just go directly to crowd-sourcing without first bothering with a classification. Readers might then just speculate without any guidelines on what struck them about the author's perspective. Experiments with crowd-sourcing in the absence of a controlled vocabulary tend to find that a very wide diversity of terms is used. And without guidance many readers may fail to reflect on important dimensions of perspective. It might be far more intriguing for amateur classifiers to address rhetorical strategy than discipline or theory applied, but potential readers may nevertheless be more concerned with the latter. A manageable classification such as that developed in this paper seems likely to guide classifiers to more productive ends.

## 7.0 Concluding remarks

This paper has outlined a classification of authorial perspective. A feasible set of dimensions and possibilities along dimensions was established and justified. The classification utilizes for the most part terms already present within general subject classifications. If a synthetic approach is taken, then, authorial perspective can be classified without requiring a significant expansion in the schedules of any general classification.

We briefly addressed practical considerations in the preceding section. Though these are significant there are strategies that should make it practicable to classify many/most works in terms of authorial perspective. The feasibility (or not) of such strategies can only be established empirically.
